# Chapter 2

# Semantics of IMP [Lecture 2–4]

Version of February 8, 2023

**Summary** We summarize the big-step semantics of IMP, and consider some simple examples of reasoning about semantic equivalences. We then show totality of (arithmetic and boolean) expression evaluation, and determinism of both expression evaluation and command execution. Finally, we formalize and show equivalence of the big-step semantics to a small-step semantics.

# 2.1 Big-step IMP semantics and simple reasoning

## 2.1.1 Recapitulation of the IMP language

We consider IMP more or less as defined in FSoPL, though with a short-circuit semantics of conjunction and disjunction, to make the corresponding proof cases a bit more interesting.

**Syntax** The abstract syntax of the language is as follows. Note that we distinguish syntactically between numbers  $n \in \mathbf{Z}$  and numerals  $\overline{n} \in \mathbf{AExp}$ .

```
n \in \mathbf{Z} = \{\dots, -1, 0, 1, 2, \dots\}

X \in \mathbf{Loc} = \{x, y, z, sum, count, \dots\}

a ::= \overline{n} \mid X \mid a_0 + a_1 \mid a_0 - a_1 \mid a_0 \times a_1

t ::= \mathbf{true} \mid \mathbf{false}

b ::= t \mid a_0 = a_1 \mid a_0 \le a_1 \mid \neg b_0 \mid b_0 \wedge b_1

c ::= \mathbf{skip} \mid X := a \mid c_0; c_1 \mid \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1 \mid \mathbf{while} \ b \ \mathbf{do} \ c_0
```

(For the *concrete* syntax, we must also specify the usual precedence and associativity rules for the infix operators, as well as the precise lexical rules for well-formed location names.) For the sake of illustration, we have omitted disjunction as a separate syntactic construct, opting instead to define it as syntactic sugar:  $b_0 \vee b_1 \stackrel{\text{def}}{\equiv} \neg(\neg b_0 \wedge \neg b_1)$ .

$$\begin{split} & \text{Judgment } \overline{ \left\langle a,\sigma \right\rangle \downarrow n } \\ & \text{EA-Num} : \overline{ \left\langle n,\sigma \right\rangle \downarrow n } \\ & \text{EA-Loc} : \overline{ \left\langle X,\sigma \right\rangle \downarrow \sigma(X) } \\ & \text{EA-Plus} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EA-Minus} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EA-Times} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EB-CST} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_0 } \\ & \text{EB-CST} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_0 } \\ & \text{EB-EQT} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EB-EQF} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EB-LeQT} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EB-LeQT} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow n_0 } \quad \left\langle a_1,\sigma \right\rangle \downarrow n_1 } \\ & \text{EB-NEGT} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-NEGT} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-NEGF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-NDF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-ANDF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-ANDF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-ANDF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EB-ANDF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow true } \\ & \text{EC-SKIP} : \overline{ \left\langle skip,\sigma \right\rangle \downarrow \sigma } \\ & \text{EC-ASSIGN} : \overline{ \left\langle x,\sigma \right\rangle \downarrow \sigma } \\ & \text{EC-IFT} : \overline{ \left\langle b,\sigma \right\rangle \downarrow true } \quad \left\langle a_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{EC-Heller} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow \sigma' } \\ & \text{EC-WHILEF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow \sigma' } \\ & \text{EC-WHILEF} : \overline{ \left\langle b_0,\sigma \right\rangle \downarrow \sigma' } \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{EC-WilleF} : \overline{ \left\langle a_0,\sigma \right\rangle \downarrow \sigma' } \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right\rangle \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right) \downarrow \sigma' \\ & \text{While } b \text{ do } c_0,\sigma \right$$

Figure 2.1: Big-step semantics of IMP

**Semantics** Like in FSoPL, we use  $\sigma \in \Sigma = \mathbf{Loc} \to \mathbf{Z}$  to range over stores. The big-step semantics is then also essentially as in FSoPL, modulo notational details. In particular, we use  $\downarrow$  instead of  $\to$  for the evaluation judgments, and we write  $\sigma[X \mapsto n]$ , rather than  $\sigma[n/X]$ , for the updated store that maps X to n, and all other locations Y to  $\sigma(Y)$ . For easy reference, the judgments and rules are given in Figure 2.1.

### 2.1.2 Reasoning about semantic equivalence

With the formal semantics of expressions and commands settled, we can also define the notions of  $semantic \ equivalence$  of syntactic phrases. Following FSoPL, we introduce the following notation:

$$a \sim a' \equiv \forall \sigma, n. \langle a, \sigma \rangle \downarrow n \Leftrightarrow \langle a', \sigma \rangle \downarrow n$$
  
$$b \sim b' \equiv \forall \sigma, t. \langle b, \sigma \rangle \downarrow t \Leftrightarrow \langle b', \sigma \rangle \downarrow t$$
  
$$c \sim c' \equiv \forall \sigma, \sigma'. \langle c, \sigma \rangle \downarrow \sigma' \Leftrightarrow \langle c', \sigma \rangle \downarrow \sigma'$$

For instance, arithmetic expressions a and a' are considered semantically equivalent whenever, in all stores  $\sigma$ , if a can evaluate to an integer n, then so can a', and vice versa. This relationship is sometimes informally and *imprecisely* paraphrased as "a and a' always evaluate to the same result"; but such a paraphrase only makes sense if we have already established that, in every store, any expression must evaluate to exactly one number. While this (as we will show) is indeed the case for arithmetic expressions in IMP, it wouldn't necessarily hold in a larger language, and so it is important that we stick to the formal definition of semantic equivalence in discussion and proofs.

To show that two expressions (or commands) are equivalent, we consider how the left-hand side of the  $\Leftrightarrow$  could have been derived by the semantic rules, and check that the right-hand side is then also derivable; and then we establish the same property from right to left. Sometimes this is straightforward: for example, to verify the expectable equivalence  $a_0 + a_1 \sim a_1 + a_0$ , for all  $a_0$  and  $a_1$ , we just observe that any derivation of  $\langle a_0 + a_1, \sigma \rangle \downarrow n$  must have the shape

EA-Plus 
$$\frac{\vdots}{\langle a_0, \sigma \rangle \downarrow n_0} \quad \vdots \quad \vdots \\ \langle a_1, \sigma \rangle \downarrow n_1 \\ \langle a_0 + a_1, \sigma \rangle \downarrow n_0 + n_1}$$
,

where  $n = n_0 + n_1$ . Putting together the two subderivations in the opposite order, and exploiting that, for mathematical integers,  $n_0 + n_1 = n_1 + n_0$ , we can easily construct a corresponding derivation of  $\langle a_1 + a_0, \sigma \rangle \downarrow n$ . The converse direction is essentially identical. However, when more than one rule may apply in a situation, we have to proceed more systematically. To illustrate, let us show the following simple but useful fact:

**Theorem 2.1** For all boolean expressions b, we have  $b \wedge \text{true} \sim b$ .

**Proof.** Let any b be given, and let  $\sigma$  and t be an arbitrary store and truth value, respectively; we must show that  $\langle b \wedge \mathbf{true}, \sigma \rangle \downarrow t \Leftrightarrow \langle b, \sigma \rangle \downarrow t$ . Recalling that  $\Leftrightarrow$  is an abbreviation for two separate implications, we first show that, if  $\langle b \wedge \mathbf{true}, \sigma \rangle \downarrow t$  by some derivation  $\mathcal{E}$ , then there exists a derivation  $\mathcal{E}'$  of  $\langle b, \sigma \rangle \downarrow t$ .

Note that we know nothing about b, other than that it is a well formed boolean expression; thus, it might at first seem that we need to separately consider all the 5 possible shapes that b could have. Fortunately, this is not necessary: looking at the EB-??? rules in the semantics, there are only two whose conclusion is an  $\land$ -expression (EB-ANDT and EB-ANDF), and hence there are only two overall shapes that the derivation  $\mathcal{E}$  can take:

• Case  $\mathcal{E} = \text{EB-AndT} \frac{\langle b, \sigma \rangle \downarrow \mathbf{true}}{\langle b \wedge \mathbf{true}, \sigma \rangle \downarrow t}$ , for some subderivations  $\mathcal{E}_0$  and  $\mathcal{E}_1$ . In this case, again looking at the rules, we see that the subderivation  $\mathcal{E}_1$  could only have used the rule EB-Cst (with t in the rule taken as  $\mathbf{true}$ ), so we must further have

$$\mathcal{E}_1 = {\scriptscriptstyle \mathrm{EB-Cst}} rac{}{\langle \mathbf{true}, \sigma 
angle \downarrow \mathbf{true}} \,.$$

But this means that we must also have  $t = \mathbf{true}$  in the original derivation  $\mathcal{E}$ ; and thus we can simply use  $\mathcal{E}_0$  as the required derivation  $\mathcal{E}'$  of  $\langle b, \sigma \rangle \downarrow t$ .

• Case  $\mathcal{E} = \text{EB-Andf} \frac{\langle b, \sigma \rangle \downarrow \mathbf{false}}{\langle b \wedge \mathbf{true}, \sigma \rangle \downarrow \mathbf{false}}$ , for some subderivation  $\mathcal{E}_0$ . In this case, we evidently have  $t = \mathbf{false}$ , and so again, we can directly use  $\mathcal{E}_0$  as  $\mathcal{E}'$ .

This concludes the  $\Rightarrow$  direction of the proof, but we also need to show  $\Leftarrow$ , i.e., that if we have a derivation  $\mathcal{E}'$  of  $\langle b, \sigma \rangle \downarrow t$ , then we can construct an  $\mathcal{E}$  of  $\langle b \wedge \mathbf{true}, \sigma \rangle \downarrow t$ . Here, because we know nothing about the shape of b, we can no longer usefully split into cases on how the derivation  $\mathcal{E}'$  could look. Instead, however, we can exploit that there are only two possibilities for the result t:

• Case  $t = \mathbf{true}$ . Then  $\mathcal{E}'$  is actually a derivation of  $\langle b, \sigma \rangle \downarrow \mathbf{true}$ , and so we can use EB-ANDT and EB-Cst to construct  $\mathcal{E}$ :

$$\mathcal{E} = { ext{EB-AndT}} rac{\langle b, \sigma 
angle \downarrow \mathbf{true}}{\langle b \wedge \mathbf{true}, \sigma 
angle \downarrow \mathbf{true}} rac{\langle b \wedge \mathbf{true}, \sigma 
angle \downarrow \mathbf{true}}{\langle b \wedge \mathbf{true}, \sigma 
angle \downarrow \mathbf{true}}$$

(This also happens to be the *only* way we could construct  $\mathcal{E}$ , but that observation is *not* relevant to the proof; we just need to find *at least one* usable derivation.)

• Case t =false. Here our derivation  $\mathcal{E}'$  shows  $\langle b, \sigma \rangle \downarrow$ false, and so we can use it with EB-ANDF to build:

$$\mathcal{E} = {}_{\mathrm{EB-ANDF}} rac{\mathcal{E}'}{\langle b, \sigma 
angle \downarrow \mathbf{false}} \ \mathcal{E} = {}_{\mathrm{CB-ANDF}} rac{\langle b, \sigma 
angle \downarrow \mathbf{false}}{\langle b \wedge \mathbf{true}, \sigma 
angle \downarrow \mathbf{false}}$$

Note that, at no point in the proof, did we implicitly or explicitly rely on the given b evaluating to some unique boolean result; rather, the proof in both directions established (with somewhat different arguments) that if one of the boolean expressions  $b \wedge \mathbf{true}$  and

b can evaluate to some truth value t, then the other can also evaluate to that value – and emphatically not that "both  $b \wedge \mathbf{true}$  and b must evaluate to the same t".

A similar, but slightly more involved, analysis—synthesis argument can be used to show the following semantic equivalence between commands, often called "loop unrolling":

Theorem 2.2 For all boolean expressions b and commands  $c_0$ , we have the equivalence while b do  $c_0$   $\sim$  if b then  $(c_0;$  while b do  $c_0$ ) else skip.

**Proof.** (See also Proposition 2.8 in FSoPL, keeping in mind the differences in notation.) ( $\Rightarrow$  direction): We assume that we have a derivation  $\mathcal{E}$  of  $\langle c, \sigma \rangle \downarrow \sigma'$ , and we must construct an  $\mathcal{E}'$  of  $\langle c', \sigma \rangle \downarrow \sigma'$ . Looking at the execution rules for **while**-commands, we see that  $\mathcal{E}$  must have one of the following two shapes:

• Case 
$$\mathcal{E} = \text{EC-WHILEF} \frac{\langle b, \sigma \rangle \downarrow \text{false}}{\langle \text{while } b \text{ do } c_0, \sigma \rangle \downarrow \sigma}$$
, so  $\sigma' = \sigma$ .

Then we can take, exploiting that  $(c_0; \mathbf{while} \ b \ \mathbf{do} \ c_0) \equiv (c_0; c)$  in c':

$$\mathcal{E}' = {}_{ ext{EC-Iff}} rac{\mathcal{E}_0}{\langle \mathbf{if} \; b \; \mathbf{then} \; (c_0; c) \; \mathbf{else} \; \mathbf{skip}, \sigma 
angle \downarrow \sigma}{\langle \mathbf{olse} \; b \; \mathbf{then} \; (c_0; c) \; \mathbf{olse} \; \mathbf{skip}, \sigma 
angle \downarrow \sigma} \; .$$

• Case 
$$\mathcal{E} = \text{EC-WhileT} \frac{\mathcal{E}_0}{\langle b, \sigma \rangle \downarrow \text{true}} \frac{\mathcal{E}_1}{\langle c_0, \sigma \rangle \downarrow \sigma''} \frac{\mathcal{E}_2}{\langle c, \sigma'' \rangle \downarrow \sigma'}$$
 (for some  $\sigma''$ ).

Here we can build  $\mathcal{E}'$  as follows:

$$\mathcal{E}' = \text{EC-IfT} \frac{\langle b, \sigma \rangle \downarrow \mathbf{true}}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'} \frac{\mathcal{E}_1}{\langle c_0, \sigma' \rangle \downarrow \sigma'} \frac{\mathcal{E}_2}{\langle c, \sigma'' \rangle \downarrow \sigma'}}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'}.$$

(Note that we are formally splitting into cases based on which rule was used for  $\mathcal{E}$ , not on what  $truth\ value\ b$  evaluated to; the two notions merely happen to coincide here.)

( $\Leftarrow$  direction): We now assume given an  $\mathcal{E}'$  of  $\langle c', \sigma \rangle \downarrow \sigma'$ , and we must construct an  $\mathcal{E}$  of  $\langle c, \sigma \rangle \downarrow \sigma'$ . Since c' is an **if**-command,  $\mathcal{E}'$  must have one of the following two shapes:

• Case 
$$\mathcal{E}' = \text{EC-IFT} \frac{\mathcal{E}'_0}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'}$$

Then, since there is only one execution rule for sequence-commands, we know that  $\mathcal{E}'_1$  must itself have the following shape:

$$\mathcal{E}'_{1} = \text{EC-SeQ} \frac{\langle c_{0}, \sigma \rangle \downarrow \sigma''}{\langle c_{0}; c, \sigma \rangle \downarrow \sigma'} \frac{\mathcal{E}'_{11}}{\langle c, \sigma'' \rangle \downarrow \sigma'} \text{ (for some } \sigma'').$$

And then we can put the various subderivations together using EC-WHILET:

$$\mathcal{E} = { text{EC-WHILET}} rac{\mathcal{E}_0'}{\langle b, \sigma 
angle \downarrow ext{true}} rac{\mathcal{E}_{10}'}{\langle c_0, \sigma 
angle \downarrow \sigma''} rac{\mathcal{E}_{11}'}{\langle c, \sigma'' 
angle \downarrow \sigma'} \,.$$

• Case 
$$\mathcal{E}' = \text{EC-Iff} \frac{\mathcal{E}'_0}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'}{\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \downarrow \sigma'}.$$

Here, since there is only one execution rule for  $\mathbf{skip}$ ,  $\mathcal{E}'_1$  must have used it, and therefore have the following shape:

$$\mathcal{E}'_1 = \text{EC-Skip} \frac{}{\langle \mathbf{skip}, \sigma \rangle \downarrow \sigma},$$

so, in particular, we know that  $\sigma' = \sigma$ . And with that knowledge, we can again build the required  $\mathcal{E}$ , now using the EC-WHILEF rule:

$$\mathcal{E} = {}_{ ext{EC-WHILEF}} rac{\mathcal{E}_0'}{\langle b, \sigma 
angle \downarrow ext{false}} \ rac{\langle b, \sigma 
angle \downarrow ext{false}}{\langle ext{while } b ext{ do } c_0, \sigma 
angle \downarrow \sigma} \,.$$

Again, the arguments in both directions, while superficially similar, are by no means identical, and there's no way to reliably prove both directions in  $\sim$  at once – especially since there's no a priori guarantee that  $c_0$  necessarily terminates, let alone that c and c' do. In particular, it would be plain *incorrect* to paraphrase the theorem as "c and c' in the same initial store always execute to the same final store."

# 2.2 Inductive reasoning about IMP semantics

In proofs about programming-language semantics we will frequently be reasoning about sorts whose elements are tree-like structures. Most obviously, sorts representing *program phrases*, such as arithmetic expressions, have abstract syntax trees as elements; but also *derivations* of various judgments, such as expression evaluation, are evidently trees, with rule instances as nodes (and axioms making up the leaf nodes). In this section, we will first briefly sketch some general principles for reasoning about trees, and then consider how these principles can be used to show some useful facts about the semantics.

# 2.2.1 Inductive reasoning principles

Essentially, proofs by induction are a refinement of proofs by case analysis over elements of some sort, in which we may additionally assume that the property we are proving has already been shown for all "smaller" elements of the sort.

For ordinary (mathematical) induction, this corresponds to proving P(n), for an arbitrary natural number n, by considering cases: n must be either 0 or n' + 1 for some smaller natural number n'; so it suffices to show P(0) (the base case), and P(n' + 1)

under the assumption that we already know P(n'). This additional assumption is called the *induction hypothesis* (IH).

The same idea applies to other sorts that can usefully be seen as sets of tree-like structures, most notably syntactic phrases and derivation trees. For example, to show that P(a) holds for all  $a \in \mathbf{AExp}$  by  $structural\ induction$ , we need to show the following cases:

- Case  $a = \overline{n}$ , for some integer n, i.e., that  $P(\overline{n})$  holds for all  $n \in \mathbb{Z}$ . Almost always, the proof will not depend on the actual number n, but merely on it being an integer.
- Case a = X, for some  $X \in \mathbf{Loc}$ . Likewise, the actual location X will often not matter for the proof. (But see, e.g., Theorem 2.8)in the next section.) This case, together with the preceding one, are considered the base cases in the proof, because they do not appeal to the IH.
- Case  $a = a_0 + a_1$ , for some subexpressions  $a_0$  and  $a_1$ , where we may assume that we already know  $P(a_0)$  and  $P(a_1)$ . We usually say that we apply the IH on  $a_0$  or  $a_1$ . Note that, in the simplest form of structural induction, we can only directly assume that P holds for  $a_0$  and  $a_1$  themselves, but not necessarily for any further subexpressions of those.
- Cases  $a = a_0 a_1$ ,  $a = a_0 \times a_1$ . These will often be proved completely analogously to the case for addition, in which case it suffices to just say so, even in a *semi-formal* proof. (In a completely formal/machine-checkable proof, however, we would need to mechanically copy the exact argument two more times with minor changes. If this would require nontrivial effort, or if there were significantly more operators in the language, we would typically first restructure the grammar by introducing an additional grammar symbol  $\oplus$ , where  $\oplus \in \{+, -, \times, \ldots\}$ , and take  $a ::= \cdots \mid a_0 \oplus a_1$ ; then all operators could be properly dealt with in a single case in the induction on the structure of a, with any operator-specific arguments separated out into a separate proof by cases for  $\oplus$ .)

In the IMP grammar, the three tree-structured syntactic sorts are "simply recursive": for example, the alternatives in the grammar of boolean expressions b may contain occurrences of arithmetic expressions a, as well as other boolean subexpressions, but arithmetic expressions cannot contain booleans. This means that, in an inductive proof of Q(b) for all b, we may use the already completed proof of  $\forall a. P(a)$  in, say, the base case  $b = (a_0 \leq a_1)$ , just as the base  $P(\overline{n})$  might itself have been proved by a separate mathematical induction on n (if numeric constants were restricted to be non-negative).

In more complex languages, on the other hand, two or more syntactic sorts may be defined "mutually recursively". For example, we might extend the grammar of arithmetic expressions with a C-style conditional expression,  $a := \cdots \mid b ? a_0 : a_1$ . For such a variant language, we would need to show  $\forall a. P(a)$  and  $\forall b. Q(b)$  together by mutual induction, covering all the alternatives for a and b in a single, combined proof, but still adhering to the principle that we may apply the (relevant parts of the) IH to the immediate subcomponents of the expression being considered in each case. Thus, the only base cases here would be the truly atomic  $a = \overline{n}$ , a = X, and b = t.

Finally, the principle of induction also applies to other finite-tree structures than syntactic phrases, most notably to *derivation trees*. That is, when doing a case analysis on the shape on the derivation, based on the last (i.e., bottom-most) rule used, we may assume that the property being proved has already been established for all the relevant subderivations of the given one.

A key caveat for inductive proofs is that we must always explicitly state up front, before commencing the case analysis, what exactly we are showing (this, of course, also applies even to non-inductive proofs), what element we are doing the induction on, and by what principle (mathematical induction, structural induction (simple or mutual), induction on derivations, etc.) And whenever the subsequent proof appeals to "the IH", it must be unambiguously checkable that the IH is indeed being applied to a proper constituent of the phrase or tree we are analyzing, and not to some unrelated other element of the same sort, whether given as a parameter to the proof, or previously constructed as part of the proof.

Strengthening the induction hypothesis Frequently, the statement of a theorem that we want to establish is not *directly* suitable for a proof by induction. Instead, we must first prove a stronger, or more general, statement, from which the original one follows as a special case. For example, in the context of mathematical induction, suppose all variables range over the natural numbers, and we have a function  $f: \mathbf{N} \times \mathbf{N} \to \mathbf{N}$ , about which we know *only* that it satisfies the following two equations:

$$f(0,y) = y (2.1)$$

$$f(x+1,y) = f(x,y+1);$$
 (2.2)

and we want to show that, for all  $n : \mathbf{N}$ , f(n,0) = n. More schematically, let us define  $P(n) \equiv (f(n,0) = n)$ , and we want to show  $\forall n. P(n)$ . If we attempt to prove this directly by induction, for the base case n = 0, we need to show f(0,0) = 0, which does follow immediately from (2.1) (by taking y = 0). However, for the inductive case n = n' + 1, we must show f(n' + 1, 0) = n' + 1, but from (2.2) we only know that f(n' + 1, 0) = f(n', 1), while the IH gives us f(n', 0) = n', and those two equations are not enough to complete the argument.

But let us instead prove, for all naturals n, the more general property  $Q(n) \equiv \forall m. f(n,m) = n+m$ ; then Q(n) will clearly give us P(n), by instantiating the m as 0. For the inductive proof of  $\forall n. Q(n)$ , we now have the two cases:

- Case n = 0. We must show, for all m, that f(0, m) = 0 + m, which we get directly from (2.1), by taking y = m and using the basic properties of addition.
- Case n = n' + 1, and our IH says that Q(n'), i.e., that  $\forall m. f(n', m) = n' + m$ . Then we have, for all m,

$$f(n,m) = f(n'+1,m) = {}^{(2.2)} f(n',m+1) = {}^{IH} n' + (m+1) = (n'+1) + m = n+m$$

Here, we have marked explicitly where we used the second equation for f, as well as the IH; the others follow directly from the case-assumption n = n' + 1 and simple arithmetic.

Complete induction For completeness, let us note that there exist various "stronger" notions of induction, in which we may apply the IH not only to the immediate subcomponents of the element being analyzed, but to any "strictly smaller" elements of the sort. What can be meaningfully regarded as smaller, depends on the sort. For example, for induction over natural numbers, we may use the principle of complete, or course-of-values, induction: it says that, when proving P(n), we may assume that we have already established P(n') for all n' < n, not only for n' = n - 1 (when  $n \neq 0$ ). Likewise, for reasoning about trees, we can say that a tree t' is smaller than t not only when t is an immediate child of t's root node, but also when, e.g, t' is any proper subtree of t, or even if t' just contains strictly fewer nodes than t. The crucial property we require is that the ordering relation  $t_0 > t_1 > t_2 > \cdots$ . Clearly, the arithmetic ordering relation  $t_0 > t_1 > t_2 > \cdots$ . Clearly, the arithmetic ordering relation  $t_0 > t_1 > t_2 > \cdots$ . Clearly, the arithmetic ordering relation  $t_0 > t_1 > t_2 > \cdots$ . Clearly, the arithmetic ordering relation  $t_0 > t_1 > t_2 > \cdots$  on the natural numbers (but not on the integers!) satisfies that, as do the relations "is a proper subtree of" and "has strictly fewer nodes than". In this course, however, we will not need those stronger variants of induction.

### 2.2.2 Totality of expression evaluation

As a first inductive proof about the IMP semantics, let us show totality of the evaluation judgment for arithmetic expressions:

**Theorem 2.3** For every arithmetic expression a and store  $\sigma$ , there exists an integer n for which we can construct a derivation  $\mathcal{E}$  of  $\langle a, \sigma \rangle \downarrow n$ .

**Proof.** By induction on the *syntax* (or *structure*) of a:

• Case  $a = \overline{n_0}$ , for some  $n_0$ . Then we can simply take  $n = n_0$ , and construct:

$$\mathcal{E} = \text{EA-Num} \frac{}{\langle \overline{n_0}, \sigma \rangle \downarrow n_0} \,.$$

This  $\mathcal{E}$  is evidently a derivation of  $\langle a, \sigma \rangle \downarrow n$ , as required.

• Case a = X. Then we take  $n = \sigma(X)$ , and use the rule for looking up locations:

$$\mathcal{E} = \text{EA-Loc} \frac{1}{\langle X, \sigma \rangle \downarrow \sigma(X)}$$
.

• Case  $a = a_0 + a_1$ . By IH on  $a_0$ , there exists an  $n_0$  and a derivation  $\mathcal{E}_0$  of  $\langle a_0, \sigma \rangle \downarrow n_0$ ; likewise, by IH on  $a_1$ , there exist  $n_1$  and  $\mathcal{E}_1$  of  $\langle a_1, \sigma \rangle \downarrow n_1$ . But then we can take  $n = n_0 + n_1$ , and use the addition rule to construct:

$$\mathcal{E} = \text{EA-Plus} \frac{\mathcal{E}_0}{\langle a_0, \sigma \rangle \downarrow n_0} \frac{\mathcal{E}_1}{\langle a_1, \sigma \rangle \downarrow n_1}.$$

• Cases  $a = a_0 - a_1$  and  $a = a_0 \times a_1$ . Completely analogous to  $a = a_0 + a_1$ .

Note that if we had integer division in the language, with syntax  $a := \cdots \mid a_0 \operatorname{\mathbf{div}} a_1$ , and evaluation rule

EA-DIVNZ: 
$$\frac{\langle a_0, \sigma \rangle \downarrow n_0}{\langle a_0 \operatorname{\mathbf{div}} a_1, \sigma \rangle \downarrow |n_0/n_1|} (n_1 \neq 0)$$
,

we would *not* be able to show the theorem: in the inductive case for  $a = a_0 \operatorname{\mathbf{div}} a_1$ , the IH would still give us derivations of  $\langle a_0, \sigma \rangle \downarrow n_0$  and  $\langle a_1, \sigma \rangle \downarrow n_1$ , but we would not always be able to put those together into the desired conclusion, because there is no applicable rule for the case where  $n_1 = 0$ .

Knowing that expression evaluation is total allows us to show additional semantic equivalences, such as  $\overline{0} \times a \sim \overline{0}$ . Here, the left-to-right direction of the biimplication in  $\sim$  always holds, but for the right-to-left one, we need to know that every a evaluates to some number, even if that number does not matter for the ultimate value of  $\overline{0} \times a$ .

Similarly, we can show:

**Theorem 2.4** For every boolean expression b and store  $\sigma$ , there exists a truth value t and a derivation  $\mathcal{E}$  of  $\langle b, \sigma \rangle \downarrow t$ .

**Proof.** By induction on the syntax of b. The cases are:

• Case  $b = t_0$ , for some  $t_0$ . Then we simply take  $t = t_0$  and, using the rule that boolean constants evaluate to themselves,

$$\mathcal{E} = \text{eb-cst} \frac{}{\langle t_0, \sigma \rangle \downarrow t_0} \,.$$

- Case  $b = (a_0 = a_1)$ . By Theorem 2.3 on  $a_0$  (note: not by IH), we get a derivation  $\mathcal{E}_0$  of  $\langle a_0, \sigma \rangle \downarrow n_0$  for some integer  $n_0$ . Likewise, by the same theorem on  $a_1$ , we get  $\mathcal{E}_1$  of  $\langle a_1, \sigma \rangle \downarrow n_1$  for some  $n_1$ . Now there are two possibilities:<sup>1</sup>
  - Subcase  $n_0 = n_1$ . Then we can take  $n = n_0$  (which also makes  $n = n_1$ ),  $t = \mathbf{true}$ , and use the first rule for equality tests to construct:

$$\mathcal{E} = \text{EB-EQT} rac{\mathcal{E}_0}{\langle a_0, \sigma \rangle \downarrow n} rac{\mathcal{E}_1}{\langle a_1, \sigma \rangle \downarrow n}}{\langle a_0 = a_1, \sigma \rangle \downarrow \mathbf{true}}.$$

- Subcase  $n_0 \neq n_1$ . Then we can use the other equaliy-test rule directly, because its side condition is satisfied, and construct:

$$\mathcal{E} = \text{EB-EQF} \frac{\langle a_0, \sigma \rangle \downarrow n_0}{\langle a_0 = a_1, \sigma \rangle \downarrow \text{false}}.$$

<sup>&</sup>lt;sup>1</sup>Note that this assertion does *not* make the proof non-constructive: We are not using the general LEM here, but the much weaker domain-specific axiom,  $\forall n, n' : \mathbf{Z}. n = n' \lor n \neq n'$ , which says that the equality relation on integers is *decidable*. On the other hand, in a constructive logic, there is no axiom like  $\forall \sigma, \sigma' : \Sigma. \sigma = \sigma' \lor \sigma \neq \sigma'$  because two infinite-domain functions – even if they are total and computable – cannot in general be tested for equality in finite time.

- Case  $b = (a_0 \le a_1)$ . Analogous to the above, again exploiting that at least one (in fact, exactly one, though that's not important here) of the relations  $n_0 \le n_1$  or  $n_0 > n_1$  will hold for any pair of integers  $n_0$  and  $n_1$ .
- Case  $b = \neg b_0$ . By the IH on  $b_0$ , we get a derivation  $\mathcal{E}_0$  of  $\langle b_0, \sigma \rangle \downarrow t_0$  for some  $t_0$ . The grammar of truth values tells us that  $t_0$  must be one of **true** or **false**. In the former subcase, we take t =**false** and use the relevant negation rule to construct:

$$\mathcal{E} = {}_{\mathrm{EB-NEGT}} rac{\mathcal{E}_0}{\langle \neg b_0, \sigma 
angle \downarrow \mathbf{true}};$$

the latter subcase  $(t_0 = false)$  is analogous, using the EB-NegF rule instead.

- Case  $b = b_0 \wedge b_1$ . By IH on  $b_0$ , we get an  $\mathcal{E}_0$  of  $\langle b_0, \sigma \rangle \downarrow t_0$  for some  $t_0$ . Again there are only two possibilities for  $t_0$ :
  - Subcase  $t_0 = \mathbf{true}$ . By IH on  $b_1$  we obtain  $\mathcal{E}_1$  of  $\langle b_1, \sigma \rangle \downarrow t_1$  for some  $t_1$ . Now, taking  $t = t_1$ , we can use rule EB-ANDT to construct:

$$\mathcal{E} = {}_{\mathrm{EB-ANDT}} rac{egin{aligned} \mathcal{E}_0 & \mathcal{E}_1 \\ egin{aligned} \langle b_0, \sigma 
angle \downarrow \mathbf{true} & \langle b_1, \sigma 
angle \downarrow t_1 \end{aligned}}{\langle b_0 \wedge b_1, \sigma 
angle \downarrow t_1} \,.$$

- Subcase  $t_0 =$ false. In this case, we do not even need to use the IH on  $b_1$ , but we can directly take t =false and use the other conjunction rule:

$$\mathcal{E} = {}_{\mathrm{EB ext{-}ANDF}} rac{\mathcal{E}_0}{\langle b_0, \sigma 
angle \downarrow \mathbf{false}} \,.$$

There is no analogous totality theorem for command execution: in general, it is not the case that, for any command c and store  $\sigma$ , there exists a derivation of  $\langle c, \sigma \rangle \downarrow \sigma'$  for some  $\sigma'$ . For consider, e.g., c = while true do skip, and suppose that there exists at least one derivation of  $\langle$  while true do skip,  $\sigma_0 \rangle \downarrow \sigma_1$  for some  $\sigma_0$  and  $\sigma_1$ . In general, there might be several different derivations of the judgment, so let us pick a minimal one (for example, with respect to the total number of rule applications, or the length of the longest branch in the derivation tree), and call it  $\mathcal{E}_0$ . Since c is a while-command, and there is only one possible rule each for evaluating true and executing skip,  $\mathcal{E}_0$  must necessarily have the following shape:

$$\mathcal{E}_{0} = \text{EC-WhileT} \frac{\langle \mathbf{true}, \sigma_{0} \rangle \downarrow \mathbf{true}}{\langle \mathbf{true}, \sigma_{0} \rangle \downarrow \mathbf{true}} \qquad \frac{\text{EC-Skip}}{\langle \mathbf{skip}, \sigma_{0} \rangle \downarrow \sigma_{0}} \qquad \langle \mathbf{while} \ \mathbf{true} \ \mathbf{do} \ \mathbf{skip}, \sigma_{0} \rangle \downarrow \sigma_{1}}{\langle \mathbf{while} \ \mathbf{true} \ \mathbf{do} \ \mathbf{skip}, \sigma_{0} \rangle \downarrow \sigma_{1}}$$

for some subderivation  $\mathcal{E}'_0$ . But  $\mathcal{E}'_0$  is evidently strictly smaller than  $\mathcal{E}_0$ , while having exactly the same conclusion, which contradicts that  $\mathcal{E}_0$  was minimal. Therefore, there can be no such  $\mathcal{E}_0$  in the first place, and thus  $\langle \mathbf{while true do skip}, \sigma_0 \rangle \downarrow \sigma_1$  is not derivable.

We can, however, show that all of IMP's semantic judgments (evaluation of arithmetic and boolean expressions, and execution of commands) are *deterministic*, i.e., return at most one result.

### 2.2.3 Determinism of evaluation and command execution

We start by formulating determinism for arithmetic expressions. The proof is fairly similar to that of totality:

**Theorem 2.5** If  $\langle a, \sigma \rangle \downarrow n$ , and also  $\langle a, \sigma \rangle \downarrow n'$ , then n = n'.

**Proof.** Let  $\mathcal{E}$  be the derivation of  $\langle a, \sigma \rangle \downarrow n$ , and  $\mathcal{E}'$  of  $\langle a, \sigma \rangle \downarrow n'$ . The proof proceeds by induction on the syntax of a. The cases are:

• Case  $a = \overline{n_0}$ . Since there is only one rule for evaluation of numerals, we must have

$$\mathcal{E} = \text{EA-Num} \frac{}{\langle \overline{n_0}, \sigma \rangle \downarrow n_0},$$

and thus  $n = n_0$ . Analogously, since the above is also the only possible shape for  $\mathcal{E}'$ , we must have  $n' = n_0$ . But then, by symmetry and transitivity of mathematical equality, we get  $n = n_0 = n'$  as required.

• Case a = X. Again, since there is only one rule for evaluating locations, it must be the case that

$$\mathcal{E} = \mathcal{E}' = \text{Ea-Loc} \frac{1}{\langle X, \sigma \rangle \downarrow \sigma(X)}$$

and thus  $n = \sigma(X) = n'$ .

• Case  $a = a_0 + a_1$ . Since evaluation of an addition expression could only have ended in a use of rule EA-Plus, we must have, for some  $\mathcal{E}_0$ ,  $\mathcal{E}_1$ ,  $\mathcal{E}'_0$ , and  $\mathcal{E}'_1$ :

$$\mathcal{E} = \text{EA-Plus} \frac{\mathcal{E}_0}{\langle a_0, \sigma \rangle \downarrow n_0} \frac{\mathcal{E}_1}{\langle a_0 + a_1, \sigma \rangle \downarrow n_0} \quad \text{and} \quad \mathcal{E}' = \text{EA-Plus} \frac{\mathcal{E}'_0}{\langle a_0, \sigma \rangle \downarrow n'_0} \frac{\mathcal{E}'_1}{\langle a_0 + a_1, \sigma \rangle \downarrow n'_0 + n'_1}$$

with  $n = n_0 + n_1$  and  $n' = n'_0 + n'_1$ . But by IH on  $a_0$  with  $\mathcal{E}_0$  and  $\mathcal{E}'_0$ , we get  $n_0 = n'_0$ ; and by IH on  $a_1$  with  $\mathcal{E}_1$  and  $\mathcal{E}'_1$ ,  $n_1 = n'_1$ , so by usual mathematical reasoning, also  $n = n_0 + n_1 = n'_0 + n'_1 = n'$ .

• The cases for subtraction and multiplication are analogous.

Like totality, deterministic evaluation of expressions is not a given. In particular, the semantics may be (deliberately or accidentally) underspecified, so that certain expressions may evaluate to unpredictable results. The language C is notorious for this, including, e.g., when accessing uninitialized local variables in a function, indexing arrays out of bounds, or even overflowing signed integer arithmetic (though in practice, these days, virtually all C implementations use a two's complement representation without overflow detection). As a simple example in an IMP context, we could extend the previously introduced integer-division operator with another rule, saying that an attempted division by zero is allowed to return an arbitrary result:

EA-DIVZ: 
$$\frac{\langle a_0, \sigma \rangle \downarrow n_0 \qquad \langle a_1, \sigma \rangle \downarrow 0}{\langle a_0 \operatorname{\mathbf{div}} a_1, \sigma \rangle \downarrow n}.$$

Note that the n in the conclusion does not appear anywhere else in the rule, meaning that it may be instantiated with any integer (not necessarily the same even in repeated uses of EA-DivZ) in a derivation. Such an underspecified semantics may make the compiler's job a bit easier, and sometimes allows it to generate slightly faster code, but often at a considerable cost for portability and reproducibility. Most newer imperative languages, such as Java, take great care to ensure that the expected evaluation results are completely specified (possibly as throwing an exception) in all situations.

We need determinism of expression evaluation to prove, e.g., the semantic equivalence  $\overline{2} \times a \sim a + a$ . Here the left-to-right direction holds even if expression evaluation is not necessarily deterministic (or total); but for the right-to-left one, we need to know that the two copies of a on the RHS can only evaluate to the same number n, in order to construct a derivation showing that the LHS evaluates to  $2 \times n$ .

Similarly, we can show:

**Theorem 2.6** If  $\langle b, \sigma \rangle \downarrow t$ , and also  $\langle b, \sigma \rangle \downarrow t'$ , then t = t'.

The proof is left as an exercise.

Although command execution in IMP is also deterministic, we cannot actually show it by induction on the syntactic structure of the command. The reason is that, in the case pertaining to **while**-commands, the command in the last premise of rule EC-WhileT is not a *proper* subcommand of the original one. Of course, the failure to account for just this one case in a proof by induction on the syntax of c means that the almost-complete proof is invalid, even if the result itself holds. We can, however, prove it in a different way:

**Theorem 2.7** If  $\langle c, \sigma_0 \rangle \downarrow \sigma_1$  (by some derivation  $\mathcal{E}$ ), and also  $\langle c, \sigma_0 \rangle \downarrow \sigma'_1$  (by  $\mathcal{E}'$ ), then  $\sigma_1 = \sigma'_1$ .

**Proof.** By induction on the derivation  $\mathcal{E}$ . The cases are:

• Case  $\mathcal{E} = \text{EC-Skip} \frac{1}{\langle \mathbf{skip}, \sigma_0 \rangle \downarrow \sigma_0}$ , so  $c = \mathbf{skip}$  and  $\sigma_1 = \sigma_0$ .

Since there is only one rule for  $\mathbf{skip}$ -commands, we know that  $\mathcal{E}'$  must also have the shape

$$\mathcal{E}' = \text{EC-Skip} \frac{}{\langle \mathbf{skip}, \sigma_0 \rangle \downarrow \sigma_0},$$

and thus  $\sigma'_1 = \sigma_0$ . And therefore we have  $\sigma_1 = \sigma_0 = \sigma'_1$ .

• Case  $\mathcal{E} = \text{EC-Assign} \frac{\langle a, \sigma_0 \rangle \downarrow n}{\langle X := a, \sigma_0 \rangle \downarrow \sigma_0[X \mapsto n]}$ , so c = (X := a) and  $\sigma_1 = \sigma_0[X \mapsto n]$ . Again, since there is only one rule for assignment commands, we must have

$$\mathcal{E}' = \text{EC-Assign} \frac{\langle a, \sigma_0 \rangle \downarrow n'}{\langle X := a, \sigma_0 \rangle \downarrow \sigma_0[X \mapsto n']},$$

for some subderivation  $\mathcal{E}'_0$ , and  $\sigma'_1 = \sigma_0[X \mapsto n']$ . But by Theorem 2.5 on  $\mathcal{E}_0$  and  $\mathcal{E}'_0$ , we get n = n', and hence also  $\sigma_1 = \sigma_0[X \mapsto n] = \sigma_0[X \mapsto n'] = \sigma'_1$ , as required.

• Case 
$$\mathcal{E} = \text{EC-Seq} \frac{\mathcal{E}_0}{\langle c_0, \sigma_0 \rangle \downarrow \sigma_2} \frac{\mathcal{E}_1}{\langle c_1, \sigma_2 \rangle \downarrow \sigma_1}$$
, so  $c = (c_0; c_1)$ .

Since EC-SEQ is the only rule for executing sequence-commands, the only possible shape of  $\mathcal{E}'$  is:

$$\mathcal{E}' = \text{EC-Seq} \frac{\mathcal{E}'_0}{\langle c_0, \sigma_0 \rangle \downarrow \sigma'_2} \frac{\mathcal{E}'_1}{\langle c_1, \sigma'_2 \rangle \downarrow \sigma'_1}.$$

Now, by IH on  $\mathcal{E}_0$  with  $\mathcal{E}'_0$ , we get that  $\sigma_2 = \sigma'_2$ . But that means that  $\mathcal{E}'_1$  is also a derivation of  $\langle c_1, \sigma_2 \rangle \downarrow \sigma'_1$ . And thus by IH on  $\mathcal{E}_1$  with  $\mathcal{E}'_1$  (which evidently both talk about the same command and starting store), we get  $\sigma_1 = \sigma'_1$ , as required.

• Case 
$$\mathcal{E} = \text{EC-IFT} \frac{\langle b, \sigma_0 \rangle \downarrow \text{true}}{\langle \text{if } b \text{ then } c_0 \text{ else } c_1, \sigma_0 \rangle \downarrow \sigma_1}, \text{ so } c = \text{if } b \text{ then } c_0 \text{ else } c_1.$$

Unlike in the previous cases, more than one rule applies for the execution of **if**-commands. Hence, there are a priori two possibilities for the shape of  $\mathcal{E}'$ :

- Subcase 
$$\mathcal{E}' = \text{EC-IFT} \frac{\langle b, \sigma_0 \rangle \downarrow \mathbf{true}}{\langle \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma_0 \rangle \downarrow \sigma_1'}{\langle \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma_0 \rangle \downarrow \sigma_1'}$$
, i.e.,  $\mathcal{E}'$  also ended in EC-IFT.

In this case, by IH on  $\mathcal{E}_1$  with  $\mathcal{E}'_1$ , we get that  $\sigma_1 = \sigma'_1$ , as required. (Note that we did not use the subderivation  $\mathcal{E}'_0$  for anything.)

- Subcase 
$$\mathcal{E}' = \text{EC-IFF} \frac{\langle b, \sigma_0 \rangle \downarrow \text{false}}{\langle \text{if } b \text{ then } c_0 \text{ else } c_1, \sigma_0 \rangle \downarrow \sigma'_1}, \text{ i.e., } \mathcal{E}' \text{ ended in EC-IFF.}$$
This subcase is not ally impossible. For by determinism of boolean expression

This subcase is actually impossible. For by determinism of boolean expressions (Theorem 2.6) on  $\mathcal{E}_0$  and  $\mathcal{E}'_0$ , we get that **true** = **false**, which is a contradiction – from which anything follows, including in particular that  $\sigma_1 = \sigma'_1$ . (Which is just as well, since  $\mathcal{E}_1$  and  $\mathcal{E}'_1$  actually talk about different commands here, so we couldn't use the IH on them.)

 $\bullet$  The case where  $\mathcal{E}$  ends with EC-IFF is completely analogous to the previous one.

• Case 
$$\mathcal{E} = \text{EC-WHILEF} \frac{\langle b, \sigma_0 \rangle \downarrow \text{ false}}{\langle \text{while } b \text{ do } c_0, \sigma_0 \rangle \downarrow \sigma_0}$$
, so  $c = \text{while } b \text{ do } c_0$ , and  $\sigma_1 = \sigma_0$ .

Like for **if**-commands, for this c, there are a priori two possibilities for the shape of  $\mathcal{E}'$ ; but by determinism of boolean expressions again, the subcase where  $\mathcal{E}'$  uses EC-WhileT is impossible, so we must also have

$$\mathcal{E}' = ext{EC-WHILEF} rac{\langle b, \sigma_0 
angle \downarrow ext{false}}{\langle ext{while } b ext{ do } c_0, \sigma_0 
angle \downarrow \sigma_0},$$

so also  $\sigma_1' = \sigma_0$ , and thus  $\sigma_1 = \sigma_0 = \sigma_1'$  as required.

• Case 
$$\mathcal{E} = \text{EC-WhileT} \frac{\langle b, \sigma_0 \rangle \downarrow \mathbf{true}}{\langle c_0, \sigma_0 \rangle \downarrow \sigma_2} \frac{\mathcal{E}_1}{\langle c_0, \sigma_0 \rangle \downarrow \sigma_2} \frac{\mathcal{E}_2}{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma_2 \rangle \downarrow \sigma_1} \frac{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma_0 \rangle \downarrow \sigma_1}{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma_0 \rangle \downarrow \sigma_1}$$

Analogously to the previous case, the subcase where  $\mathcal{E}'$  uses EC-WhileF is impossible, so we know that  $\mathcal{E}'$  must have the shape:

$$\mathcal{E}' = \text{ec-whilet} rac{\mathcal{E}'_0}{\langle b, \sigma_0 
angle \downarrow ext{true}} rac{\mathcal{E}'_1}{\langle c_0, \sigma_0 
angle \downarrow \sigma'_2} rac{\mathcal{E}'_1}{\langle ext{while } b ext{ do } c_0, \sigma'_2 
angle \downarrow \sigma'_1}.$$

Now, by IH on  $\mathcal{E}_1$  with  $\mathcal{E}'_1$ , we get that  $\sigma_2 = \sigma'_2$ . Hence,  $\mathcal{E}'_2$  is also a derivation of  $\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma_2 \rangle \downarrow \sigma'_1$ . And thus, by IH on  $\mathcal{E}_2$  with  $\mathcal{E}'_2$ , we finally get that  $\sigma_1 = \sigma'_1$ .

### 2.2.4 Definitions by induction

Much like we can *prove* propositions by induction, we can generalize the notion of *defining* functions by cases, to allow total functions on a sort to be defined in terms of themselves, as long as there is no true circularity. For instance, the usual factorial function  $(!): \mathbf{N} \rightarrow \mathbf{N}$ , traditionally written as a postfix operator, could be defined by:

$$n! = \begin{cases} 1 & \text{if } n = 0 \\ n \times n'! & \text{if } n = n' + 1 \end{cases}$$

Note that, unlike recursive definitions in functional programs (which may, in general, define only *partial* functions), a proper definition by induction may only apply the function to evidently "smaller" (in the same sense as for proofs) arguments on the RHS.

Much like for proofs, if a function has more than one argument, we must clearly specify which one the induction is on. For example, the exponentiation function  $m^n$  for natural numbers can be defined by induction on n, by the pair of equations:

$$m^0 = 1$$

$$m^{n'+1} = m \times m^{n'}$$

Here, we have evidently given exactly one equation for each possibility of n.

Similarly, we can define functions by induction on other tree-structured sorts. For example, the function size, counting the number of nodes (including leaves) in the syntax tree of an arithmetic expression, is given by:

$$size$$
 :  $\mathbf{AExp} \to \mathbf{N}$   
 $size(\overline{n}) = 1$   
 $size(X) = 1$   
 $size(a_0 + a_1) = 1 + size(a_0) + size(a_1)$   
: (analogously for  $+$  and  $\times$ )

The codomain (i.e., result) sort of an inductively defined function need not be numeric, or even tree-like. For example, we can define the (necessarily finite) set of locations occurring in an arithmetic expression a:

$$locs : \mathbf{AExp} \to \mathcal{P}_{fin}(\mathbf{Loc})$$

$$locs(\overline{n}) = \emptyset$$

$$locs(X) = \{X\}$$

$$locs(a_0 + a_1) = locs(a_0) \cup locs(a_1)$$

$$\vdots$$

Definitions and proofs by induction often go hand in hand. For example, we can prove that, if two stores agree on at least the locations occurring in some arithmetic expression a, then a will evaluate identically in both:

**Theorem 2.8** For all  $\sigma$  and  $\sigma'$ , if  $\forall X. X \in locs(a) \Rightarrow \sigma(X) = \sigma'(X)$ , then  $\langle a, \sigma \rangle \downarrow n \Leftrightarrow \langle a, \sigma' \rangle \downarrow n$ .

**Proof.** By structural induction on a. It clearly suffices to show just the  $\Rightarrow$  direction, as the other one is completely analogous.

- Case  $a = \overline{n_0}$ . Then  $locs(a) = locs(\overline{n_0}) = \emptyset$ , so the requirement on  $\sigma$  and  $\sigma'$  is vacuously satisfied. The derivation of  $\langle \overline{n_0}, \sigma \rangle \downarrow n$  can only have used EA-Num, so we must have  $n = n_0$ , and then we can immediately construct an analogous derivation of  $\langle \overline{n_0}, \sigma' \rangle \downarrow n$ , by another use of EA-Num.
- Case a = X. Here,  $locs(a) = \{X\}$ , so we know that  $\sigma(X) = \sigma'(X)$ . Now,  $\langle X, \sigma \rangle \downarrow n$  must have used EA-Loc, so  $n = \sigma(X) = \sigma'(X)$ , which we again can use to rebuild  $\langle X, \sigma' \rangle \downarrow n$ .
- Case  $a = a_0 + a_1$ . Here,  $locs(a) = locs(a_0) \cup locs(a_1)$ . The derivation  $\mathcal{E}$  of  $\langle a_0 + a_1, \sigma \rangle \downarrow n$  must have used EA-Plus, so we have subderivations  $\mathcal{E}_0$  of  $\langle a_0, \sigma \rangle \downarrow n_0$  and  $\mathcal{E}_1$  of  $\langle a_1, \sigma \rangle \downarrow n_1$ , and  $n = n_0 + n_1$ . From the characterization of locs(a), we know that  $\sigma$  and  $\sigma'$  in particular also agree for all  $X \in locs(a_0) \subseteq locs(a)$ , and so by IH on  $a_0$  with  $\mathcal{E}_0$ , we get a derivation  $\mathcal{E}'_0$  of  $\langle a_0, \sigma' \rangle \downarrow n_0$ . Analogously, we get an  $\mathcal{E}'_1$  of  $\langle a_1, \sigma' \rangle \downarrow n_1$ , and we can put those together by EA-Plus to get the desired  $\mathcal{E}'$  of  $\langle a_0 + a_1, \sigma' \rangle \downarrow n_0 + n_1$ . The cases for subtraction and multiplication proceed in the same way.

Similarly, for any command c, we can define  $locs_L(c)$ , the set of locations occurring anywhere in c as the LHS of an assignment command; we can then show, now by induction on derivations, that this gives us an upper bound on the set of locations whose values might be changed by an execution of c, i.e., if  $X \notin locs_L(c)$  and  $\langle c, \sigma \rangle \downarrow \sigma'$ , then  $\sigma'(X) = \sigma(X)$ .

We will return to definitions by structural induction in the chapter on denotational semantics, later in the course.

# 2.3 Small-step semantics of IMP, and equivalence of the semantics

The big-step semantics we have seen so far is intuitive and well suited for many kinds of formal reasoning about the behavior of IMP programs. It is also fairly straightforward to adapt to extensions and variants of IMP (though some conceptually simple modifications may require wide-ranging changes to the core judgment forms). However, it has a couple of intrinsic shortcomings that make it problematic for certain applications, most notably:

- It does not distinguish between the possible failures of a program to yield a result. In particular, there is no formal difference between evaluation getting stuck because of a missing rule to cover a particular case (for example, an attempted division by zero if we only include the EA-DivNZ rule), and divergence, where a successful derivation would need to be infinitely large (e.g., when trying to execute while true do skip). In many situations, we can safely ignore the difference, or rework the semantics to allow it to return and propagate an explicit error result (much like a non-catchable exception). However, for some applications, such as showing type soundness, it is rather more convenient to express the semantics in such a way that certain error situations are represented as explicitly stuck derivations.
- It is poorly suited for specifying the semantics of multi-threaded languages, where we want to express that independent command executions may happen concurrently, with the threads communicating by exchanging messages (like in Erlang) and/or through a shared store (like in Java/C#, or POSIX Threads for C). Here, we want to say that two or more computations may proceed in an arbitrarily interleaved fashion, which is awkward to express in terms of a judgment that only returns the final result of an evaluation or execution.

For such situations, we may instead express the semantics in a *small-step* style, conceptually specifying how a program execution proceeds incrementally from an initial configuration to a final one (if any). Crucially, however, we will be able to show that the two semantics still define the same language, only with the small-step one making a finer distinction between programs that *fail* to finish execution for whatever reason.

## 2.3.1 Small-step semantics

We formulate the small-step semantics of IMP slightly differently from FSoPL Section 2.6. The essential changes (apart from using  $\rightarrow$  instead of  $\rightarrow_1$ ) are:

- For expressions, we choose to make it explicit in the shape of the semantic judgment that evaluation of an arithmetic or boolean expression cannot change the store. This also demonstrates how a small-step semantics can maintain some manifestly invariant data, rather than making it all part of the configuration.
- For commands, we only operate with one shape of configurations,  $\langle c, \sigma \rangle$ . FSoPL distinguishes syntactically between finished and non-finished configurations, which makes it a bit awkward to state some results concisely.

• We define the reflexive-transitive closure of the step relations as explicit judgments, given by inference rules. This tends to make the proofs more uniform, since everything is now proved by induction on derivations.

The judgments and rules are shown in Figure 2.2. We see that each single-step rule is either a *computation rule* (no premises, and a name ending in a letter) which says *how* to step something, or a *context rule* (one premise, and a name ending in a digit), saying *where* something may be stepped. Note also how the strict separation between numerals and numbers allows us to maintain a distinction between "syntactic" and "semantic" addition operators in rules like SA-Plus.

### 2.3.2 Equivalence for arithmetic expressions

We aim to show that  $\langle a, \sigma \rangle \downarrow n$  iff  $\sigma \vdash a \to^* \overline{n}$ . As in most nontrivial semantic equivalences, the two directions of the bi-implication involve rather different proofs.

### From big-step to small-step derivations

This is the conceptually simpler direction. Before we begin the proof proper, we first establish that, for any fixed  $\sigma$ , the relation  $\sigma \vdash \cdot \rightarrow^* \cdot$  is indeed transitive:

**Lemma 2.9** If  $\sigma \vdash a \rightarrow^* a'$  (by SS) and  $\sigma \vdash a' \rightarrow^* a''$  (by SS'), then  $\sigma \vdash a \rightarrow^* a''$  by some SS''.

**Proof.** Simple induction on the derivation SS. Its possible shapes are:

- Case  $SS = SSA-ZERO \frac{}{\sigma \vdash a \to^* a}$ . Then a' = a, so the second assumption SS' can be used directly as the required derivation SS'' of  $\sigma \vdash a \to^* a''$ .
- Case  $SS = \text{SSA-MORE} \frac{\sigma \vdash a \to a''' \qquad \sigma \vdash a''' \to^* a'}{\sigma \vdash a \to^* a'}$ . Then, by IH on  $SS_0$  with SS', we get a derivation  $SS'_0$  of  $\sigma \vdash a''' \to^* a''$ . And taking that together with the first step  $S_0$ , we can construct the required derivation of  $\sigma \vdash a \to^* a''$ :

$$\mathcal{SS}'' = \text{SSA-MORE} \frac{\sigma \vdash a \rightarrow a''' \qquad \mathcal{SS}'_0}{\sigma \vdash a \rightarrow^* a''} \,.$$

Judgment 
$$\sigma \vdash a \rightarrow a'$$
:

(no rules for 
$$\overline{n}$$
: already fully evaluated) SA-Loc:  $\frac{}{\sigma \vdash X \to \overline{\sigma(X)}}$ 

$$SA-PLUS1: \frac{\sigma \vdash a_0 \to a_0'}{\sigma \vdash a_0 + a_1 \to a_0' + a_1} \qquad SA-PLUS2: \frac{\sigma \vdash a_1 \to a_1'}{\sigma \vdash \overline{n_0} + a_1 \to \overline{n_0} + a_1'}$$
$$SA-PLUS: \frac{\sigma \vdash \overline{n_0} + \overline{n_1} \to \overline{n_0} + a_1}{\sigma \vdash \overline{n_0} + \overline{n_1} \to \overline{n_0} + n_1}$$

(analogous rule sets for  $a_0 - a_1$  and  $a_0 \times a_1$  omitted)

Judgment  $\sigma \vdash a \rightarrow^* a'$ :

SSA-ZERO: 
$$\frac{\sigma \vdash a \to^* a}{\sigma \vdash a \to^* a'}$$
 SSA-MORE:  $\frac{\sigma \vdash a \to a'' \quad \sigma \vdash a'' \to^* a'}{\sigma \vdash a \to^* a'}$ 

Judgment  $\sigma \vdash b \rightarrow b'$  (incomplete, left as an exercise):

SB-And1: 
$$\frac{\sigma \vdash b_0 \to b_0'}{\sigma \vdash b_0 \land b_1 \to b_0' \land b_1}$$

SB-ANDT : 
$$\frac{}{\sigma \vdash \mathbf{true} \land b_1 \rightarrow b_1}$$
 SB-ANDF :  $\frac{}{\sigma \vdash \mathbf{false} \land b_1 \rightarrow \mathbf{false}}$ 

Judgment  $\sigma \vdash b \to^* b'$ : analogous to  $\sigma \vdash a \to^* a'$ 

Judgment  $\langle c, \sigma \rangle \to \langle c', \sigma' \rangle$ :

(No rules for **skip**: already fully executed)

$$\begin{aligned} & \text{SC-Assign1}: \frac{\sigma \vdash a \to a'}{\langle X := a, \sigma \rangle \to \langle X := a', \sigma \rangle} & \text{SC-Assign}: \frac{}{\langle X := \overline{n}, \sigma \rangle \to \langle \mathbf{skip}, \sigma[X \mapsto n] \rangle} \\ & \text{SC-SeQ1}: \frac{\langle c_0, \sigma \rangle \to \langle c'_0, \sigma' \rangle}{\langle c_0; c_1, \sigma \rangle \to \langle c'_0; c_1, \sigma' \rangle} & \text{SC-SeQ}: \frac{}{\langle \mathbf{skip}; c_1, \sigma \rangle \to \langle c_1, \sigma \rangle} \\ & \text{SC-If1}: \frac{}{\langle \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \to \langle \mathbf{if} \ b' \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle} \end{aligned}$$

$$\text{SC-IFT}: \frac{}{\langle \text{if true then } c_0 \text{ else } c_1, \sigma \rangle \to \langle c_0, \sigma \rangle} \quad \text{SC-IFF}: \frac{}{\langle \text{if false then } c_0 \text{ else } c_1, \sigma \rangle \to \langle c_1, \sigma \rangle}$$

SC-WHILE: 
$$\overline{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma \rangle \rightarrow \langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; \mathbf{while} \ b \ \mathbf{do} \ c_0) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle}$$

Judgment  $\langle c, \sigma \rangle \to^* \langle c', \sigma' \rangle$ :

$$\text{SSC-Zero}: \frac{\langle c, \sigma \rangle \to^* \langle c, \sigma \rangle}{\langle c, \sigma \rangle \to^* \langle c, \sigma \rangle} \qquad \text{SSC-More}: \frac{\langle c, \sigma \rangle \to \langle c'', \sigma'' \rangle}{\langle c, \sigma \rangle \to^* \langle c', \sigma' \rangle}$$

Figure 2.2: Small-step semantics of IMP

Further, we can show that the *context rules*, such as SA-Plus1, also "extend" from single steps to multi-step sequences:

**Lemma 2.10 (for** SA-Plus1) If  $\sigma \vdash a_0 \rightarrow^* a'_0$  (by SS), then for any  $a_1$ , also  $\sigma \vdash a_0 + a_1 \rightarrow^* a'_0 + a_1$  (by some SS').

**Proof.** Simple induction on the derivation SS. The case where SS uses SSA-ZERO, i.e.,  $a'_0 = a_0$ , is immediate, since SS' can then also use SSA-ZERO for the expression  $a_0 + a_1$ . And for a non-empty SS,

case 
$$SS = SSA-MORE \frac{S_0}{\sigma \vdash a_0 \to a_0''} \frac{SS_0}{\sigma \vdash a_0'' \to^* a_0'}$$
,

the IH on  $SS_0$  gives us a derivation  $SS'_0$  of  $\sigma \vdash a''_0 + a_1 \rightarrow^* a'_0 + a_1$ , so by also using SA-PLUS1 on the first step of SS, we can construct the required:

$$\mathcal{SS}' = \frac{\mathcal{S}_0}{\text{SA-Plus1}} \frac{\sigma \vdash a_0 \to a_0''}{\sigma \vdash a_0 + a_1 \to a_0'' + a_1} \frac{\mathcal{SS}_0'}{\sigma \vdash a_0' + a_1 \to^* a_0' + a_1} \cdot \mathcal{SS}_0'$$

$$\mathcal{SS}' = \text{SSA-MORE} \frac{\sigma \vdash a_0 + a_1 \to a_0'' + a_1}{\sigma \vdash a_0 + a_1 \to^* a_0' + a_1}.$$

Naturally, completely analogous lemmas hold for the other context rules. In the following, rather than explicitly stating such lemmas, we will often just refer to them implicitly with phrases like "by repeated application of SA-Plus2 to the steps of  $\mathcal{SS}$ "; but remember that, formally, each such argument involves proving (if we hadn't already) and applying a small result about the relevant context rule.

We can now state and prove the main theorem:

**Theorem 2.11** If  $\langle a, \sigma \rangle \downarrow n$ , then  $\sigma \vdash a \rightarrow^* \overline{n}$ .

**Proof.** By induction on the derivation  $\mathcal{E}$  of  $\langle a, \sigma \rangle \downarrow n$ , we construct the required derivation  $\mathcal{SS}$  of  $\sigma \vdash a \to^* \overline{n}$ . We encounter the following cases for the shape of  $\mathcal{E}$ :

- Case  $\mathcal{E} = \text{EA-Num} \frac{1}{\langle \overline{n}, \sigma \rangle \downarrow n}$ , so  $a = \overline{n}$ . Here we can directly take  $\mathcal{SS} = \text{SSA-Zero} \frac{1}{\sigma \vdash \overline{n} \rightarrow^* \overline{n}}$ .
- Case  $\mathcal{E} = \text{EA-Loc} \frac{1}{\langle X, \sigma \rangle \downarrow \sigma(X)}$ , so a = X and  $n = \sigma(X)$ .

Here we need three rule applications to construct SS:

$$SS = SSA-MORE \frac{\overline{\sigma \vdash X \to \overline{\sigma(X)}}}{\sigma \vdash X \to \overline{\sigma(X)}} \frac{SSA-ZERO}{\overline{\sigma \vdash \overline{\sigma(X)}} \to^* \overline{\sigma(X)}}{\sigma \vdash X \to^* \overline{\sigma(X)}}.$$

In the remainder of these notes, we will just use without explicit comment that whenever we have  $\sigma \vdash a \rightarrow a'$ , then also  $\sigma \vdash a \rightarrow^* a'$ , by an application of SSA-Zero and SSA-More, as demonstrated above.

• Case 
$$\mathcal{E} = \text{EA-Plus} \frac{\mathcal{E}_0}{\langle a_0, \sigma \rangle \downarrow n_0} \frac{\mathcal{E}_1}{\langle a_1, \sigma \rangle \downarrow n_1}$$
, so  $a = a_0 + a_1$  and  $n = n_0 + n_1$ .

By IH on  $\mathcal{E}_0$ , we obtain a small-step-sequence derivation  $\mathcal{SS}_0$  of  $\sigma \vdash a_0 \to^* \overline{n_0}$ ; and step-wise application of SA-Plus1 (i.e., Lemma 2.10) on  $\mathcal{SS}_0$  gives us an  $\mathcal{SS}'_0$  showing that  $\sigma \vdash a_0 + a_1 \to^* \overline{n_0} + a_1$ .

Analogously, by the induction hypothesis on  $\mathcal{E}_1$  we get a derivation  $\mathcal{SS}_1$  of  $\sigma \vdash a_1 \to^* \overline{n_1}$ ; and using SA-PLUS2 on each step of  $\mathcal{SS}_1$ , we get a derivation  $\mathcal{SS}_1'$  of  $\sigma \vdash \overline{n_0} + a_1 \to^* \overline{n_0} + \overline{n_1}$ .

Finally, using SA-Plus, we get a one-step sequence  $SS_2$  showing  $\sigma \vdash \overline{n_0} + \overline{n_1} \rightarrow^* \overline{n_0 + n_1}$ . Concatenating  $SS'_0$ ,  $SS'_1$ , and  $SS_2$  using Lemma 2.9 (twice), we obtain the required derivation SS of  $\sigma \vdash a_0 + a_1 \rightarrow^* \overline{n_0 + n_1}$ .

• The cases for subtraction and multiplication are analogous.

### From small-step to big-step derivations

The other direction of the equivalence is more subtle. The key to getting a clean proof is formulating a suitable lemma, expressing a general relationship between small-step and big-step derivations, saying that we can "prepend" a single small step to a big-step evaluation:

**Lemma 2.12** Given a derivation S of  $\sigma \vdash a \rightarrow a'$ , and a derivation E' of  $\langle a', \sigma \rangle \downarrow n$ , then there also exists a derivation E of  $\langle a, \sigma \rangle \downarrow n$ .

**Proof.** By induction on the derivation S:

• Case 
$$S = \text{SA-Loc} \frac{1}{\sigma \vdash X \to \overline{\sigma(X)}}$$
, so  $a = X$  and  $a' = \overline{\sigma(X)}$ .

Since EA-Num is the only possible big-step rule for evaluation of the numeral a', we must have

$$\mathcal{E}' = \text{EA-Num} \frac{}{\langle \overline{\sigma(X)}, \sigma \rangle \downarrow \sigma(X)},$$

so  $n = \sigma(X)$ . And thus, we can construct the required  $\mathcal{E}$  using the big-step rule for locations:

$$\mathcal{E} = \text{EA-Loc} \frac{1}{\langle X, \sigma \rangle \downarrow \sigma(X)}$$
.

• Case 
$$S = \text{SA-Plus1} \frac{S_0}{\sigma \vdash a_0 \to a'_0}$$
, so  $a = a_0 + a_1$  and  $a' = a'_0 + a_1$ .

Since only EA-Plus could have been used in the big-step evaluation of the addition expression a', the given big-step derivation  $\mathcal{E}'$  must have the shape:

$$\mathcal{E}' = \text{EA-Plus} \frac{\mathcal{E}'_0}{\langle a'_0, \sigma \rangle \downarrow n_0} \frac{\mathcal{E}_1}{\langle a_1, \sigma \rangle \downarrow n_1},$$

with  $n = n_0 + n_1$ . But then, by IH on  $S_0$  with  $\mathcal{E}'_0$ , we get a derivation  $\mathcal{E}_0$  of  $\langle a_0, \sigma \rangle \downarrow n_0$ . And thus, we can construct the required big-step derivation  $\mathcal{E}$  that starts already from  $a_0 + a_1$ :

$$\mathcal{E} = \text{EA-Plus} rac{\mathcal{E}_0}{\langle a_0, \sigma \rangle \downarrow n_0} rac{\mathcal{E}_1}{\langle a_1, \sigma \rangle \downarrow n_1}}{\langle a_0 + a_1, \sigma \rangle \downarrow n_0 + n_1}.$$

• Case 
$$S = \text{SA-Plus2} \frac{\sigma \vdash a_1 \to a_1'}{\sigma \vdash \overline{n_0} + a_1 \to \overline{n_0} + a_1'}$$
, so  $a = \overline{n_0} + a_1$  and  $a' = \overline{n_0} + a_1'$ .

Like above, by considering the shape of a', the only possible shape for  $\mathcal{E}'$  must be:

$$\mathcal{E}' = \frac{\text{EA-Num}}{\text{EA-Plus}} \frac{\mathcal{E}'_1}{\langle \overline{n_0}, \sigma \rangle \downarrow n_0} \qquad \langle a'_1, \sigma \rangle \downarrow n_1 \\ \langle \overline{n_0} + a'_1, \sigma \rangle \downarrow n_0 + n_1$$

Again, we have  $n = n_0 + n_1$ ; and by IH on  $S_1$  with  $E'_1$ , we get a derivation  $E_1$  of  $\langle a_1, \sigma \rangle \downarrow n_1$ , so we can rebuild:

$$\mathcal{E} = \frac{\text{EA-Num}}{\text{EA-Plus}} \frac{\mathcal{E}_1}{\langle \overline{n_0}, \sigma \rangle \downarrow n_0} \quad \langle a_1, \sigma \rangle \downarrow n_1}{\langle \overline{n_0} + a_1, \sigma \rangle \downarrow n_0 + n_1}.$$

• Case  $S = \text{SA-Plus} \frac{\sigma}{\sigma \vdash \overline{n_0} + \overline{n_1} \to \overline{n_0 + n_1}}$ , so  $a = \overline{n_0} + \overline{n_1}$  and  $a' = \overline{n_0 + n_1}$ .

In this case, a' is just a numeral, so  $\mathcal{E}'$  must have used EA-Num, and we have  $n = n_0 + n_1$ . But then, we can use the big-step rules for constants and addition to construct:

$$\mathcal{E} = {}^{ ext{EA-Num}} rac{\overline{\langle \overline{n_0}, \sigma 
angle \downarrow n_0}}{\overline{\langle \overline{n_0}, \sigma 
angle \downarrow \overline{n_1}}} \stackrel{ ext{EA-Num}}{\overline{\langle \overline{n_1}, \sigma 
angle \downarrow n_1}}.$$

Having done almost all the actual work in the above Lemma, we can now easily prove the converse of Theorem 2.11:

**Theorem 2.13** If  $\sigma \vdash a \rightarrow^* \overline{n}$ , then  $\langle a, \sigma \rangle \downarrow n$ .

**Proof.** By induction on the derivation SS of the assumption. The two cases are:

• Case  $SS = SSC-ZERO \xrightarrow{\sigma \vdash \overline{n} \to *\overline{n}}$ , so  $a = \overline{n}$ .

Here, the result follows directly by EA-Num,  $\overline{\langle \overline{n}, \sigma \rangle \downarrow n}$ .

• Case 
$$SS = SSC-MORE \frac{S_0}{\sigma \vdash a \to a'} \frac{SS_0}{\sigma \vdash a' \to^* \overline{n}}$$
.

Then we can use the IH on  $SS_0$  to obtain a big-step derivation of  $\langle a', \sigma \rangle \downarrow n$ . And "prepending" the step  $S_0$  to this derivation, using Lemma 2.12, gives us the required big-step derivation of  $\langle a, \sigma \rangle \downarrow n$ .

Theorems 2.11 and 2.13 together say that the big-step and small-step semantics of arithmetic expressions are equivalent. Note, however, that we will still need Lemma 2.12 itself, not only Theorem 2.13, to prove equivalence for commands.

### 2.3.3 Equivalence for boolean expressions

Once the small-step semantics of boolean expressions is correctly completed, we expect to show:

**Lemma 2.14** If  $\sigma \vdash b \to^* b'$  and  $\sigma \vdash b' \to^* b''$ , then  $\sigma \vdash b \to^* b''$ .

**Theorem 2.15** If  $\langle b, \sigma \rangle \downarrow t$ , then  $\sigma \vdash b \rightarrow^* t$ .

**Lemma 2.16** If  $\sigma \vdash b \rightarrow b'$  and  $\langle b', \sigma \rangle \downarrow t$ , then  $\langle b, \sigma \rangle \downarrow t$ .

**Theorem 2.17** *If*  $\sigma \vdash b \rightarrow^* t$ , then  $\langle b, \sigma \rangle \downarrow t$ .

The details are left as exercises.

### 2.3.4 Equivalence for commands

The proofs of equivalence for commands are similar in structure to the ones for expressions, but involve a greater variety of arguments, reflecting the greater complexities of the two semantics.

#### From big-step to small-step

Again, we will first need a concatenation lemma:

**Lemma 2.18** If 
$$\langle c, \sigma \rangle \to^* \langle c', \sigma' \rangle$$
 and  $\langle c', \sigma' \rangle \to^* \langle c'', \sigma'' \rangle$ , then  $\langle c, \sigma \rangle \to^* \langle c'', \sigma'' \rangle$ .

**Proof.** Analogous to Lemma 2.9.

We also have variants of Lemma 2.10, extending all the context rules for command execution (SC-Assign1, etc.) to multistep derivations. With those, we can show the theorem:

**Theorem 2.19** If 
$$\langle c, \sigma \rangle \downarrow \sigma'$$
, then  $\langle c, \sigma \rangle \rightarrow^* \langle \mathbf{skip}, \sigma' \rangle$ .

**Proof.** By induction on the big-step derivation  $\mathcal{E}$  of the assumption. The following cases arise: (Note that we have elided the explicit rule names in all derivations.)

• Case  $\mathcal{E} = \frac{1}{\langle \mathbf{skip}, \sigma \rangle \downarrow \sigma}$ . Here  $c = \mathbf{skip}$  and  $\sigma' = \sigma$ , and so we can construct the zero-step sequence  $\frac{1}{\langle \mathbf{skip}, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma \rangle}$ .

- Case  $\mathcal{E} = \frac{\langle a, \sigma \rangle \downarrow n}{\langle X := a, \sigma \rangle \downarrow \sigma[X \mapsto n]}$ . By Theorem 2.11 on  $\mathcal{E}_0$ , we get a derivation  $\mathcal{SS}_0$  of  $\sigma \vdash a \to^* \overline{n}$ , which we can convert to a derivation  $\mathcal{SS}'_0$  of  $\langle X := a, \sigma \rangle \to^* \langle X := \overline{n}, \sigma \rangle$  by using SC-Assign1 on each step. Moreover, SC-Assign allows us to construct a one-step sequence  $\mathcal{SS}_1$  showing  $\langle X := \overline{n}, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma[X \mapsto n] \rangle$ ; and concatenating  $\mathcal{SS}'_0$  and  $\mathcal{SS}_1$  using Lemma 2.18, we obtain the required derivation of  $\langle X := a, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma[X \mapsto n] \rangle$ .
- (The case for sequencing is left as an exercise.)

• Case 
$$\mathcal{E} = \frac{\mathcal{E}_0}{\langle b, \sigma \rangle \downarrow \text{true}} \frac{\mathcal{E}_1}{\langle c_0, \sigma \rangle \downarrow \sigma'} \frac{\langle c_0, \sigma \rangle \downarrow \sigma'}{\langle \text{if } b \text{ then } c_0 \text{ else } c_1, \sigma \rangle \downarrow \sigma'}.$$

By Theorem 2.15 on  $\mathcal{E}_0$  we get a reduction sequence  $\sigma \vdash b \to^* \mathbf{true}$ . Using SC-IF1 on each step of that, we obtain a corresponding sequence

$$\langle \text{if } b \text{ then } c_0 \text{ else } c_1, \sigma \rangle \rightarrow^* \langle \text{if true then } c_0 \text{ else } c_1, \sigma \rangle$$
,

which can be concatenated with the one-step sequence  $\langle \mathbf{if} \ \mathbf{true} \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \to^* \langle c_0, \sigma \rangle$  that we get from the SC-IFT reduction rule, and then the sequence  $\langle c_0, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma' \rangle$  from the IH on  $\mathcal{E}_1$ , to obtain the required  $\langle \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma' \rangle$ .

ullet The case where  ${\mathcal E}$  uses EC-IFF is completely analogous.

• Case 
$$\mathcal{E} = \frac{\langle b, \sigma \rangle \downarrow \text{false}}{\langle \text{while } b \text{ do } c_0, \sigma \rangle \downarrow \sigma}$$
, so  $\sigma' = \sigma$ .

Here c =while bdo  $c_0$ , so by SC-While, we get a one-step sequence:

(while 
$$b$$
 do  $c_0, \sigma$ )  $\rightarrow^*$  (if  $b$  then  $(c_0; c)$  else skip,  $\sigma$ ).

By Theorem 2.15 on  $\mathcal{E}_0$  we get a sequence  $\sigma \vdash b \to^* \mathbf{false}$ , which by stepwise uses of SC-IF1 induces a sequence

$$\langle \text{if } b \text{ then } (c_0; c) \text{ else skip}, \sigma \rangle \to^* \langle \text{if false then } (c_0; c) \text{ else skip}, \sigma \rangle$$
.

Finally, by the SC-IFF rule, we have in one step:

$$\langle \text{if false then } (c_0; c) \text{ else skip}, \sigma \rangle \rightarrow^* \langle \text{skip}, \sigma \rangle$$
.

Concatenating those three sequences together, we obtain the desired sequence  $\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma \rangle \rightarrow^* \langle \mathbf{skip}, \sigma \rangle$ .

• Case 
$$\mathcal{E} = \frac{\langle b, \sigma \rangle \downarrow \mathbf{true}}{\langle c_0, \sigma \rangle \downarrow \sigma''} \frac{\mathcal{E}_1}{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma'' \rangle \downarrow \sigma'} \frac{\mathcal{E}_2}{\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma'' \rangle \downarrow \sigma'}$$
.

Here we again have c =while bdo  $c_0$ . Like in the EC-While case, we first use the SC-While rule to get a one-step sequence:

(while 
$$b$$
 do  $c_0, \sigma$ )  $\rightarrow^*$  (if  $b$  then  $(c_0; c)$  else skip,  $\sigma$ ).

Next, by Theorem 2.15 on  $\mathcal{E}_0$  we get  $\sigma \vdash b \to^* \mathbf{true}$ , from which the iterated SC-IF1 gives us:

 $\langle \mathbf{if} \ b \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle \to^* \langle \mathbf{if} \ \mathbf{true} \ \mathbf{then} \ (c_0; c) \ \mathbf{else} \ \mathbf{skip}, \sigma \rangle$ .

Then, by the SC-IfT rule:

$$\langle \text{if true then } (c_0; c) \text{ else skip}, \sigma \rangle \rightarrow^* \langle c_0; c, \sigma \rangle$$
.

Now, by IH on  $\mathcal{E}_1$  we get  $\langle c_0, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma'' \rangle$ , from which we get, by the iterated SC-SEQ1 (with  $c_1 = c$ ):

$$\langle c_0; c, \sigma \rangle \to^* \langle \mathbf{skip}; c, \sigma'' \rangle$$
.

By SC-SEQ we have, in one step:

$$\langle \mathbf{skip}; c, \sigma'' \rangle \to^* \langle c, \sigma'' \rangle$$
.

Finally, by IH on  $\mathcal{E}_2$ , we get:

$$\langle c, \sigma'' \rangle \to^* \langle \mathbf{skip}, \sigma' \rangle$$
.

And concatenating the six displayed sequences together, we obtain the desired

$$\langle \mathbf{while} \ b \ \mathbf{do} \ c_0, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma' \rangle$$
.

### From small-step to big-step derivations

Like for expressions, the essence of the proof lies in the following lemma:

**Lemma 2.20** Given a derivation S of  $\langle c, \sigma \rangle \to \langle c', \sigma' \rangle$ , and a derivation E' of  $\langle c', \sigma' \rangle \downarrow \sigma''$ , then there also exists a derivation E of  $\langle c, \sigma \rangle \downarrow \sigma''$ .

**Proof.** By induction on the derivation S:

• Case 
$$S = \frac{S_0}{\langle X := a, \sigma \rangle \to \langle X := a', \sigma \rangle}$$
.

We have c = (X := a), c' = (X := a'), and  $\sigma' = \sigma$ . Since there is only one big-step rule for assignment commands,  $\mathcal{E}'$  must have the shape:

$$\mathcal{E}' = \frac{\mathcal{E}'_0}{\langle A', \sigma \rangle \downarrow n} \\ \langle X := a', \sigma \rangle \downarrow \sigma[X \mapsto n] ,$$

and  $\sigma'' = \sigma[X \mapsto n]$ . By Lemma 2.12 on  $\mathcal{S}_0$  and  $\mathcal{E}'_0$ , we obtain a big-step derivation  $\mathcal{E}_0$  of  $\langle a, \sigma \rangle \downarrow n$ , which we can use to construct the required execution derivation:

$$\mathcal{E} = \frac{\langle a, \sigma \rangle \downarrow n}{\langle X := a, \sigma \rangle \downarrow \sigma[X \mapsto n]}.$$

• Case 
$$S = \frac{1}{\langle X := \overline{n}, \sigma \rangle \to \langle \mathbf{skip}, \sigma[X \mapsto n] \rangle}$$
.

Here  $c=(X:=\overline{n}),\ c'=\mathbf{skip}$  and  $\sigma'=\sigma[X\mapsto n]$ . Since  $\mathcal{E}'$  must have used EC-Skip, we also have  $\sigma''=\sigma'$ . We can thus directly use EA-Num and EA-Assign to construct:

$$\mathcal{E} = \frac{\overline{\langle \overline{n}, \sigma \rangle \downarrow n}}{\langle X := \overline{n}, \sigma \rangle \downarrow \sigma[X \mapsto n]}.$$

• (The cases for SC-Seq1 and SC-Seq are left as an exercise.)

• Case 
$$S = \frac{S_0}{\langle \text{if } b \text{ then } c_0 \text{ else } c_1, \sigma \rangle \rightarrow \langle \text{if } b' \text{ then } c_0 \text{ else } c_1, \sigma \rangle}.$$

Again, we have  $\sigma' = \sigma$ . But  $c' = \mathbf{if} \ b'$  then  $c_0$  else  $c_1$ , so there are now two possibilities for how  $\mathcal{E}'$  can look, depending on which of the two big-step rules for conditionals was used:

- Subcase 
$$\mathcal{E}' = \frac{\mathcal{E}'_0}{\langle \mathbf{if} \ b' \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \downarrow \sigma''} \frac{\mathcal{E}_1}{\langle \mathbf{if} \ b' \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \downarrow \sigma''}$$

In this case, by Lemma 2.16 on the derivations  $\mathcal{S}_0$  and  $\mathcal{E}'_0$ , we obtain a derivation  $\mathcal{E}_0$  of  $\langle b, \sigma \rangle \downarrow \mathbf{true}$ , and we can then put together the required derivation  $\mathcal{E}$  as follows:

$$\mathcal{E} = \frac{\langle b, \sigma \rangle \downarrow \mathbf{true}}{\langle \mathbf{if} \ b \ \mathbf{then} \ c_0 \ \mathbf{else} \ c_1, \sigma \rangle \downarrow \sigma''}.$$

– The subcase where  $\mathcal{E}'$  ends in EC-IFF is analogous.

• Case 
$$S = \frac{1}{\langle \text{if true then } c_0 \text{ else } c_1, \sigma \rangle \to \langle c_0, \sigma \rangle}$$
.

Here  $\sigma' = \sigma$ , so we can use the supplied big-step derivation  $\mathcal{E}'$  directly to construct the required  $\mathcal{E}$ , using EB-CsT and EC-IfT:

$$\mathcal{E} = rac{\mathcal{E}'}{\langle ext{true}, \sigma 
angle \downarrow ext{true}} rac{\mathcal{E}'}{\langle c_0, \sigma 
angle \downarrow \sigma''}.$$

- ullet The case where  ${\cal S}$  uses SC-IFF is analogous.
- (The case where S uses SC-While is left as an exercise.)

And finally, we can now easily show the converse of Theorem 2.19:

**Theorem 2.21** If  $\langle c, \sigma \rangle \to^* \langle \mathbf{skip}, \sigma' \rangle$ , then  $\langle c, \sigma \rangle \downarrow \sigma'$ .

**Proof.** Analogous to the proof of Theorem 2.13: If the derivation  $\mathcal{SS}$  of the assumption uses the rule SSC-Zero, we must already have  $c = \mathbf{skip}$  and  $\sigma' = \sigma$ , and so we can use EC-Skip to obtain  $\langle c, \sigma \rangle \downarrow \sigma'$ . Otherwise,  $\mathcal{SS}$  must end in rule SSC-More, so we have subderivations  $\mathcal{S}_0$  of  $\langle c, \sigma \rangle \rightarrow \langle c'', \sigma'' \rangle$  and  $\mathcal{SS}_0$  of  $\langle c'', \sigma'' \rangle \rightarrow^* \langle \mathbf{skip}, \sigma' \rangle$ . Using the IH on  $\mathcal{SS}_0$ , we get an  $\mathcal{E}_0$  of  $\langle c'', \sigma'' \rangle \downarrow \sigma'$ , and then Lemma 2.20 on  $\mathcal{S}_0$  and  $\mathcal{E}_0$  gives us the required  $\langle c, \sigma \rangle \downarrow \sigma'$ .

### 2.4 Exercises

- 2.1. Prove Theorem 2.6 by (a) induction on syntax, or (b) induction on derivations.
- 2.2. Supply the missing cases for Theorem 2.19 and Lemma 2.20 having to do with sequencing commands  $(c_0; c_1)$ .
- 2.3. Supply the missing case for **while**-loops in Lemma 2.20. *Hint*: exploit Theorem 2.2.
- 2.4. Complete the small-step semantics in Figure 2.2 by giving all the missing rules relating to boolean expressions. (The ones for conjunction are complete, and should not be extended or modified.)
- 2.5. Prove Theorem 2.15 and Lemma 2.16 for the cases relating to conjunctions (EB-ANDT and EB-ANDF vs. SB-AND1, SB-ANDT, and SB-ANDF).
